Typical pitfalls

Edexcel GCSE Computer Science — **Embedded Systems (1CP2/01 Topic 3: Computers)**. This topic covers what embedded systems are, their key characteristics, common examples in everyday devices, and why they are used instead of general-purpose computers.

Exam questions typically ask you to **define** what an embedded system is, **identify** examples, **describe** their characteristics, and **explain** why embedded systems are used in specific contexts. The 2024 Paper 1 included questions about sensors in cars, which relates to embedded systems controlling vehicle functions. Expect questions worth 2—4 marks requiring you to link characteristics to real-world applications.

Why embedded systems matter

Embedded systems are everywhere in modern life — often invisible but essential:

- **Ubiquitous technology:** There are far more embedded systems in the world than general-purpose computers — billions are in use
- **Everyday devices:** Your washing machine, microwave, car, and smart watch all contain embedded systems
- **Internet of Things (IoT):** Smart home devices, wearables, and connected sensors all rely on embedded systems

- **Safety-critical applications:** Medical devices, aircraft systems, and car braking systems use embedded computers
- **Exam relevance:** This topic appears in Paper 1 as part of Topic 3, typically worth 2—6 marks

What you must know

This checklist covers the key exam-visible concepts from Edexcel 1CP2 Topic 3: Computers. You should be able to explain each point and apply it to exam scenarios.

- **Define** what an embedded system is and state its key characteristic (dedicated to a specific task)
- **Describe** the main characteristics of embedded systems: single purpose, built into a larger device, limited or no user interface, and often works in real time
- **Identify** examples of embedded systems in everyday devices such as washing machines, cars, traffic lights, and smart devices
- **Explain** why embedded systems are used instead of general-purpose computers for specific tasks
- **Compare** embedded systems with general-purpose computers in terms of purpose, flexibility, cost, and user interaction
- **Describe** how sensors and actuators work with embedded systems to monitor and control physical processes

> **Specification link:** This topic covers Edexcel 1CP2 Paper 1 Topic 3: Computers — specifically understanding what embedded systems are, recognising examples of embedded systems, and explaining why embedded systems are used.

Toolkit

These are the key patterns, definitions and characteristics you need to apply in exam questions.

Embedded system characteristics

Characteristic	What it means	Example
Dedicated/single purpose	Designed to perform one specific task or set of related tasks	A washing machine controller only controls washing cycles
Built into a larger device	The computer system is part of a bigger product, not a standalone computer	The processor in a microwave is hidden inside the appliance
Limited/no user interface	Often has minimal controls (buttons, small display) or runs autonomously	A thermostat may have a simple dial; a car ECU has no direct user interface
Real-time operation	Must respond to inputs immediately without noticeable delay	Anti-lock brakes must react instantly when sensors detect wheel lock

Characteristic	What it means	Example
Low power consumption	Often designed to use minimal energy, especially battery-powered devices	A fitness tracker runs for days on a small battery
Reliable and stable	Designed to run continuously without crashing or needing restarts	A pacemaker must work 24/7 for years without failure

Key definition

Embedded system: A computer system built into a larger device or machine to perform a dedicated function. It is designed for a specific purpose and is not a general-purpose computer.
Key phrase for exams: "A computer system designed to perform a **dedicated/specific function**, **built into** a larger device."

Embedded vs general-purpose comparison

Feature	Embedded system	General-purpose computer
Purpose	Single, dedicated task	Multiple, varied tasks
Flexibility	Limited — does one thing	High — can run many applications
User interface	Minimal or none	Full keyboard, mouse, monitor
Cost	Usually lower (mass produced)	Usually higher
Size	Often very small	Larger (desktop, laptop)
Power usage	Typically low	Higher
Software updates	Rare or never	Frequent
Example	Washing machine controller	Desktop PC, laptop

Common embedded system examples by category

Home appliances

- Washing machine
- Microwave oven
- Dishwasher
- Smart thermostat

Transport

- Car engine management
- Anti-lock braking system
- Airbag controller
- Sat nav system

- Digital alarm clock
- Smart TV

- Traffic lights
- Train door systems

Personal devices

- Smart watch
- Fitness tracker
- Digital camera
- Games console controller
- E-reader
- Wireless headphones

1. What are embedded systems?

An **embedded system** is a computer system that is built into a larger device to perform a specific, dedicated function. Unlike a general-purpose computer (like a laptop or desktop PC), which can run many different programs and perform varied tasks, an embedded system is designed to do one job — and do it well.

1.1 Definition and core concept

The word "embedded" means built into something else. An embedded system is "embedded" within a larger device — you typically cannot see or directly interact with the computer inside. The system is hidden from the user, working behind the scenes to control the device's functions.

Key features of the definition:

- It is a **computer system** — it has a processor, memory, and software
- It is **built into** a larger device — not a standalone computer
- It performs a **dedicated function** — designed for a specific purpose
- It is **not general-purpose** — you cannot install new applications like on a PC

1.2 Components of an embedded system

Although hidden from users, embedded systems contain the same basic components as any computer:

- **Processor:** A small, efficient CPU (often called a microcontroller) that runs the control software
- **Memory:** ROM to store the program permanently, and RAM for temporary data
- **Input devices:** Sensors that detect conditions (temperature, pressure, motion, etc.)
- **Output devices:** Actuators that cause physical actions (motors, valves, displays, buzzers)
- **Software:** The program that controls the device, often called firmware

> **Exam tip:** When asked to define an embedded system, always include these three elements: (1) it's a computer system, (2) it's built into a larger device, (3) it performs a dedicated/specific function.

1.3 The dedicated nature of embedded systems

The most important characteristic of an embedded system is that it is **dedicated** — designed for a single purpose. This is fundamentally different from a general-purpose computer:

A washing machine's embedded system:

- Controls water temperature
- Controls drum rotation speed
- Times the wash cycles
- Monitors water levels
- Controls the door lock

It **cannot** browse the internet, play games, or run a word processor. It only does washing machine tasks.

1.4 Real-time requirements

Many embedded systems must operate in **real time** — meaning they must respond to inputs immediately, without noticeable delay. This is especially important in safety-critical applications.

Examples of real-time requirements:

- **Anti-lock brakes:** Must respond within milliseconds when sensors detect wheel lock
- **Airbags:** Must inflate within 30 milliseconds of detecting a collision
- **Pacemaker:** Must deliver electrical pulses at precisely timed intervals
- **Traffic lights:** Must change at correct intervals and respond to sensors

A delay of even a fraction of a second could be dangerous or cause the system to fail in its purpose.

1.5 Embedded system diagram

```
┌──────────────────────────────────────────────────────────────────────────┐
EMBEDDED SYSTEM │ │ (Built into a larger device, e.g. washing machine) │
├──────────────────────────────────────────────────────────────────────────┤ │ │ │

```

Worked Example 1 — Defining an embedded system

Question: Define what is meant by an embedded system. [2 marks]

Model answer:
An embedded system is a computer system that is built into a larger device **(1)**. It is designed to perform a specific/dedicated function **(1)**.

Exam tip: For 2 marks, you need both parts: (1) built into something bigger, (2) dedicated purpose. Giving an example alone is not enough for a definition

question.

Worked Example 2 — Identifying embedded system characteristics

Question: State two characteristics of an embedded system. [2 marks]

Model answer:
Designed for a single/dedicated purpose **(1)**.
Has limited or no user interface **(1)**.
Also acceptable: Built into a larger device / Low power consumption / Real-time operation / Reliable and stable / Cannot run other applications

Exam tip: "State" questions require brief answers. Don't write paragraphs — just give clear, distinct points from the characteristics list.

Worked Example 3 — Explaining real-time operation

Question: Explain why embedded systems in cars often need to operate in real time. [2 marks]

Model answer:
The embedded system must respond to sensor inputs immediately/without delay **(1)**.
This is because a delay could be dangerous, for example, if anti-lock brakes did not respond instantly when wheels begin to lock **(1)**.

Exam tip: "Explain why" requires a reason. Link real-time operation to consequences of delay — especially safety in automotive examples.

Worked Example 4 — Components of an embedded system

Question: A washing machine contains an embedded system. Identify one input device and one output device that the embedded system would use. [2 marks]

Model answer:
Input device: Temperature sensor / water level sensor / pressure sensor / button on control panel **(1)**.
Output device: Motor (to turn drum) / valve (to control water) / display / buzzer **(1)**.

> **Exam tip:** Sensors are inputs (they detect conditions). Actuators like motors and valves are outputs (they cause physical actions). Don't confuse them.

2. Examples and applications

Embedded systems are found in almost every aspect of modern life. Understanding where they are used and **why** they are chosen over general-purpose computers is essential for exam success. This section explores common applications across different domains.

2.1 Home appliances

Most modern household appliances contain embedded systems that control their operations:

Washing machine

A classic example used in many exam questions. The embedded system:

- Receives input from temperature and water level sensors
- Controls the motor speed and direction for different cycle types
- Manages the water inlet and drain valves
- Times each phase of the wash cycle
- Locks the door during operation for safety

Microwave oven

The embedded system controls:

- Power levels of the magnetron (heating element)
- Timing for cooking duration
- Safety interlocks (door must be closed to operate)
- Display and user input from keypad

Smart thermostat

A modern example combining embedded systems with connectivity:

- Monitors room temperature using sensors
- Controls heating/cooling systems automatically
- Can be programmed with schedules
- May connect to the internet for remote control

> **Exam context:** When asked about home appliance embedded systems, focus on the sensors (inputs), actuators (outputs), and the specific control tasks the system performs.

2.2 Automotive systems

Modern cars contain dozens of embedded systems controlling different functions. This is a common exam topic.

Engine management system (ECU)

Controls fuel injection, ignition timing, and emissions:

- Monitors engine temperature, air intake, and throttle position
- Adjusts fuel mixture for optimal performance
- Controls emissions systems to meet regulations

Anti-lock braking system (ABS)

A safety-critical embedded system that:

- Monitors wheel speed sensors
- Detects when a wheel is about to lock
- Pulses the brakes to prevent skidding
- Must respond in real time (milliseconds)

Airbag system

Another safety-critical system:

- Monitors crash sensors (accelerometers)
- Determines if collision is severe enough to deploy
- Inflates airbag within approximately 30 milliseconds

Parking sensors

As mentioned in the 2024 exam context about car sensors:

- Use ultrasonic or radar sensors to detect obstacles
- Calculate distance to nearby objects
- Provide audio or visual warnings to the driver

> **Exam tip:** The 2024 Paper 1 asked about sensors in cars. Be ready to explain how sensors (inputs) provide data to embedded systems that then control outputs (brakes, display, warning sounds).

2.3 Other common applications

Medical devices

- **Pacemaker:** Monitors heart rhythm and delivers electrical pulses
- **Insulin pump:** Delivers precise doses of medication
- **Blood pressure monitor:** Measures and displays readings

Reliability is critical — these are life-sustaining systems.

Consumer electronics

- **Smart watch:** Tracks fitness, displays notifications
- **Digital camera:** Controls focus, exposure, image processing
- **Games controller:** Processes button inputs, motion sensing

Low power and small size are key requirements.

Infrastructure

- **Traffic lights:** Timed sequences, sensor-triggered changes
- **ATM machines:** Secure transactions, user interface
- **Vending machines:** Product selection, payment processing

Must operate reliably 24/7.

2.4 Sensors and control in embedded systems

Understanding how sensors and actuators work together in embedded systems is important for exam questions. Many embedded systems follow a **control loop** pattern:

The embedded control loop

1. **Sense:** Sensors detect the current state (temperature, speed, position, etc.)
2. **Process:** The embedded processor compares the current state to the desired state
3. **Act:** Actuators make adjustments to bring the system closer to the desired state
4. **Repeat:** The cycle continues, constantly monitoring and adjusting

Example: Central heating thermostat

A thermostat demonstrates the control loop clearly:

- **Sensor:** Temperature sensor measures room temperature
- **Process:** Embedded system compares measured temperature to the set target temperature
- **Act:** If room is too cold, signals the boiler to turn on; if warm enough, signals it to turn off
- **Repeat:** Continuously monitors and adjusts to maintain the target temperature

Example: Car cruise control

Cruise control in a car uses a similar pattern:

- **Sensor:** Speed sensor monitors current vehicle speed
- **Process:** Embedded system compares current speed to the set cruising speed
- **Act:** If too slow, increases throttle; if too fast, reduces throttle or applies brakes
- **Repeat:** Continuously adjusts to maintain the set speed

> **Exam tip:** When describing how an embedded system works, use the sense → process → act structure. This shows you understand the complete control loop, not just individual components.

2.5 Why embedded systems are used

There are several important reasons why manufacturers choose embedded systems instead of general-purpose computers:

Reason	Explanation	Example
Cost efficiency	Embedded processors are cheaper than full computers, reducing manufacturing costs	A £2 microcontroller vs a £200 computer in each washing machine
Size	Embedded systems can be made very small to fit inside devices	A fitness tracker needs a tiny processor to fit on your wrist
Power efficiency	Use less energy, important for battery-powered or always-on devices	A smart thermostat can run for months on batteries
Reliability	Simpler systems with fewer things to go wrong; don't need rebooting	A pacemaker must work continuously for years
Real-time response	Can be optimised for immediate response without OS overhead	ABS brakes must react within milliseconds
Simplicity	Only does what's needed — no unnecessary features	A microwave doesn't need to run a web browser

Worked Example 5 — Identifying embedded systems

Question: Identify two devices in a home that contain embedded systems. [2 marks]

Model answer:
Washing machine **(1)**.
Microwave oven / Smart TV / Dishwasher / Central heating thermostat **(1)**.

Exam tip: "Identify" means name or list. Choose obvious examples — washing machine is the classic. Avoid computers, tablets, or phones as these are general-purpose devices.

Worked Example 6 — Explaining why embedded systems are used

Question: Explain why an embedded system is used in a digital watch instead of a general-purpose computer. [3 marks]

Model answer:
An embedded system is smaller in size, allowing it to fit on a wrist **(1)**.
It uses less power, so the watch can run for months or years on a small battery **(1)**.
It is cheaper to manufacture, keeping the product affordable **(1)**.
Also acceptable: The watch only needs to perform a dedicated function (tell time) / More reliable / No complex operating system needed

Exam tip: "Explain why" needs reasons. Link each reason to the specific device context — size matters for wearables, power matters for batteries.

Worked Example 7 — Sensors and actuators in a car

Question: A car's embedded braking system uses sensors and actuators. Describe how they work together to prevent skidding. [3 marks]

Model answer:
Speed sensors monitor the rotation speed of each wheel **(1)**.
If a sensor detects that a wheel is about to lock/stop rotating while the car is moving, this data is sent to the embedded system **(1)**.
The embedded system activates actuators to pulse/release the brake on that wheel, preventing it from locking and skidding **(1)**.

Exam tip: Show the input → process → output sequence: sensor detects → embedded system processes → actuator responds. This demonstrates understanding of how the system works.

Worked Example 8 — Application scenario

Question: A hospital uses an embedded system in a patient monitoring device. Describe two features that make embedded systems suitable for this application. [4 marks]

Model answer:
Feature 1 — Reliability:
Embedded systems are designed to run continuously without crashing **(1)**.
This is essential because the patient monitor must work 24/7 to track vital signs without failure **(1)**.
Feature 2 — Real-time operation:
Embedded systems can respond to inputs immediately **(1)**.
If a patient's heart rate becomes dangerous, the system must trigger an alarm instantly without delay **(1)**.

Exam tip: For application scenarios, link each feature to why it matters for that specific context. Generic answers score fewer marks.

3. Comparison and evaluation

Understanding the differences between embedded systems and general-purpose computers is essential for answering comparison and evaluation questions. This section explores these differences in depth and addresses common exam question types.

3.1 Embedded vs general-purpose computers

The fundamental difference is **purpose**: embedded systems do one job, while general-purpose computers can do many different things.

General-purpose computer characteristics

A desktop PC, laptop, or tablet is general-purpose because:

- Users can install and run different applications
- It has a full operating system (Windows, macOS, Linux)
- It includes comprehensive input devices (keyboard, mouse, touchscreen)
- It has a large display for user interaction
- It can be used for word processing, gaming, browsing, programming, etc.
- Software can be updated, changed, or removed

Why the distinction matters

Exam questions often ask you to explain why a device uses an embedded system rather than a general-purpose computer. The answer usually relates to:

- **Cost:** Embedded systems are cheaper for mass production

- **Size:** Embedded systems can be much smaller
- **Power:** Embedded systems use less energy
- **Reliability:** Simpler systems are more reliable
- **Purpose:** The device only needs specific functionality

> **Exam tip:** If asked "Why not use a general-purpose computer?", reverse the question: what would be wrong with using a laptop in a washing machine? Too expensive, too big, uses too much power, and would be unnecessarily complex.

3.2 Smartphones: a special case

Smartphones are interesting because they blur the line between embedded and general-purpose systems:

Smartphone characteristics

General-purpose features:

- Users can install many different apps
- Has a full operating system (iOS, Android)
- Used for varied tasks (calls, gaming, browsing, photos)

Embedded-like features:

- Optimised for low power consumption
- Contains many embedded subsystems (camera controller, GPS, accelerometer)
- Some functions are dedicated (phone calls, sensors)

Conclusion: Smartphones are primarily general-purpose devices but contain many embedded systems within them.

3.3 Advantages and limitations

When evaluating embedded systems, consider both their benefits and constraints:

Advantages of embedded systems

- Lower cost per unit in mass production
- Smaller physical size
- Lower power consumption
- Higher reliability (fewer components to fail)
- Optimised performance for specific tasks
- Faster response times (real-time operation)

Limitations of embedded systems

- Cannot be easily reprogrammed for different tasks
- Limited or no user interface
- May be difficult to update or upgrade
- Less flexible than general-purpose computers
- May require complete replacement if requirements change

3.4 The Internet of Things (IoT)

The **Internet of Things** refers to the growing network of everyday devices that contain embedded systems connected to the internet. This provides useful context for understanding modern uses of embedded systems.

Examples of IoT devices

- **Smart home:** Thermostats, light bulbs, door locks, security cameras
- **Wearables:** Fitness trackers, smart watches
- **Health:** Connected medical monitors
- **Transport:** Connected cars, tracking systems
- **Agriculture:** Soil sensors, automated irrigation

IoT characteristics

- Embedded systems with network connectivity
- Can send and receive data over the internet
- Often controlled remotely via apps
- May collect data for analysis (e.g., energy usage)

Note: IoT is mentioned here as context for how embedded systems are used in modern devices. Security and ethical issues related to connected devices are covered separately in Topic 5: Issues and Impact.

3.5 Choosing the right system

When deciding whether to use an embedded system or a general-purpose computer, designers consider:

Question to ask	If yes → Embedded	If no → General-purpose
Is the device performing a single, specific function?	Washing machine, thermostat	Laptop, tablet
Does cost need to be minimised for mass production?	Consumer appliances	Specialised workstations
Is small size essential?	Fitness tracker, pacemaker	Desktop computer
Must it run on battery for extended periods?	Smart watch, remote sensors	Desktop PC
Is 24/7 reliability critical?	Medical devices, safety systems	Office computers

Worked Example 9 — Comparing systems

Question: Compare an embedded system in a washing machine with a general-purpose desktop computer. Give two differences. [4 marks]

Model answer:
Difference 1 — Purpose:

The embedded system is designed for a single, dedicated function (controlling the wash cycle) **(1)**.
The desktop computer can perform many different tasks (word processing, gaming, browsing) **(1)**.
Difference 2 — User interface:
The embedded system has a limited interface (buttons and a simple display) **(1)**.
The desktop computer has a full interface (keyboard, mouse, large monitor) **(1)**.

Exam tip: "Compare" means identify differences (and sometimes similarities). Structure your answer by naming each difference clearly, then explaining both sides.

Worked Example 10 — Evaluating suitability

Question: A company is designing a new fitness tracker. Explain why an embedded system would be more suitable than a general-purpose computer for this device. [3 marks]

Model answer:
An embedded system can be made small enough to fit on a wristband **(1)**.
It uses less power, allowing the device to run for days on a small battery **(1)**.
It costs less to manufacture, making the product affordable for consumers **(1)**.
Also acceptable: More reliable / Only needs dedicated function / Lighter weight

Exam tip: Match reasons to the device. For wearables: size, weight, and battery life matter most. For appliances: cost and reliability. For safety systems: reliability and speed.

Worked Example 11 — Limitations of embedded systems

Question: State two limitations of using an embedded system in a device. [2 marks]

Model answer:
The system cannot be easily reprogrammed to perform different tasks **(1)**.
It has limited or no user interface compared to a general-purpose computer **(1)**.
Also acceptable: Difficult to update/upgrade / Less flexible / May need complete replacement if requirements change

Exam tip: Limitations are the downsides — things embedded systems cannot do well. These are often the flip side of their advantages (simple = limited

flexibility).

Worked Example 12 — Connected embedded systems

Question: A smart home heating system uses an embedded system. Describe one advantage of using an embedded system and one limitation. [4 marks]

Model answer:
Advantage:
The embedded system is reliable and can run continuously without needing to be restarted **(1)**.
This means the heating system can operate 24/7 to maintain the desired temperature automatically **(1)**.
Limitation:
The embedded system is designed for a specific purpose and cannot be easily reprogrammed **(1)**.
If the homeowner wanted different features, they would likely need to replace the entire thermostat unit **(1)**.

Exam tip: When discussing advantages and limitations, link each point to the specific device context. Show you understand how the characteristic affects real-world use.

Worked examples summary

The table below summarises the 12 worked examples covered in this topic, organised by section and difficulty level.

#	Topic	Question type	Marks	Key skill
1	Definition	Define embedded system	2	Built into + dedicated purpose
2	Characteristics	State characteristics	2	List from characteristics table
3	Real-time	Explain real-time need	2	Link to safety consequences
4	Components	Identify inputs/outputs	2	Sensors = inputs, actuators = outputs
5	Examples	Identify devices	2	Name common home devices

#	Topic	Question type	Marks	Key skill
6	Reasons	Explain why embedded	3	Size, power, cost for context
7	Automotive	Describe sensor/actuator	3	Input → process → output
8	Medical	Describe suitable features	4	Link features to application
9	Comparison	Compare with general-purpose	4	Structured differences
10	Suitability	Explain suitability	3	Match reasons to device type
11	Limitations	State limitations	2	Flexibility, updates, interface
12	Smart home	Advantage and limitation	4	Link to device context

Quick reference

Key terms and definitions

Term	Definition (mark-scheme style)
Embedded system	A computer system built into a larger device, designed to perform a specific/dedicated function
General-purpose computer	A computer that can run many different applications and perform varied tasks (e.g., desktop PC, laptop)
Dedicated function	Designed to perform a single, specific task rather than multiple varied tasks
Real-time operation	Responding to inputs immediately without noticeable delay
Sensor	An input device that detects physical conditions (temperature, pressure, light, motion, etc.)
Actuator	An output device that causes physical action (motor, valve, heater, display, etc.)
Firmware	Software permanently stored in an embedded system's memory that controls its operation
Internet of Things (IoT)	Network of everyday devices containing embedded systems that connect to the internet

Term	Definition (mark-scheme style)
Microcontroller	A small, efficient processor used in embedded systems, containing CPU, memory, and I/O on one chip

Characteristics at a glance

Characteristic	Key exam phrase
Dedicated purpose	"Designed for a single/specific function"
Built-in	"Built into a larger device"
Limited interface	"Limited or no user interface"
Real-time	"Responds immediately without delay"
Low power	"Low power consumption"
Reliable	"Runs continuously without crashing"
Small size	"Small enough to fit inside devices"
Low cost	"Cheaper to manufacture"

Common examples by category

Category	Examples	Key function
Home appliances	Washing machine, microwave, dishwasher	Control cycles, timing, temperature
Automotive	ABS, airbag, engine management, sat nav	Safety systems, engine control
Personal devices	Smart watch, fitness tracker, camera	Tracking, image processing
Medical	Pacemaker, insulin pump, monitors	Life-critical monitoring and control
Infrastructure	Traffic lights, ATMs, vending machines	Public systems, transactions

Typical pitfalls

Pitfall 1 — Confusing embedded with general-purpose.
Wrong: "A laptop is an embedded system because it's portable."

Right: A laptop is a **general-purpose** computer — it can run many different applications. Embedded systems are **dedicated** to one task.

Pitfall 2 — Incomplete definitions.
Wrong: "An embedded system is a small computer."
Right: "An embedded system is a computer system **built into a larger device** to perform a **dedicated function**." Include both key elements.

Pitfall 3 — Confusing sensors and actuators.
Wrong: "A motor is a sensor in a washing machine."
Right: A motor is an **actuator** (output). **Sensors** are inputs that detect conditions (temperature, water level).

Pitfall 4 — Claiming smartphones are embedded systems.
Wrong: "A smartphone is an embedded system."
Right: Smartphones are primarily **general-purpose** devices (you can install many apps). They **contain** embedded systems (camera controller, GPS) but are not themselves embedded systems.

Pitfall 5 — Forgetting real-time in safety contexts.
Wrong: Explaining car brakes without mentioning immediate response.
Right: In safety-critical systems, always mention that the embedded system must respond **immediately** — a delay could be dangerous.

Pitfall 6 — Generic reasons without context.
Wrong: "Embedded systems are used because they're cheap and small." (no link to device)
Right: "A fitness tracker uses an embedded system because it needs to be **small enough to wear** and **run on a small battery**." Link to the specific device.

Pitfall 7 — Missing the "built into" aspect.
Wrong: "An embedded system performs a dedicated task."
Right: For full marks, also mention that it is **built into a larger device**. The embedded nature is key to the definition.

Pitfall 8 — Thinking embedded means cannot be updated.
Wrong: "Embedded systems can never be updated."
Right: Some embedded systems can receive firmware updates (e.g., car ECUs, smart home devices), though this is less common than with general-purpose computers.

Pitfall 9 — Listing too many similar examples.
Wrong: "Washing machine, dishwasher, tumble dryer" (all too similar)
Right: Choose examples from different categories to show breadth of knowledge (e.g., washing machine, car ABS, smart watch).

Pitfall 10 — Only discussing advantages.
Wrong: Only mentioning that embedded systems are cheap, small, and efficient.
Right: Be prepared to discuss **limitations** too — embedded systems are inflexible, difficult to update, and cannot perform multiple tasks like general-purpose computers.
